ABSTRACT

Objective: To determine the feasibility of a randomised controlled trial (RCT) assessing the effects of an experience-based website as a resource for the self-management of chronic asthma.

Design and setting: Feasibility, single-blind RCT in 2 regions of England. Randomisation used computer-generated random number sequence in a 1:1 ratio, after baseline data collection, to website access for 2 weeks.

Participants: Adults (age ≥18 years), with clinically diagnosed asthma as coded in their primary care electronic record, prescribed inhaled corticosteroids for at least 3 months in the previous year, were recruited from 9 general practices.

Intervention: The EXPERT asthma intervention is an interactive PC/laptop/tablet/smartphone compatible website designed with extensive input from adults with asthma. It provides experience-based information and aims to support subjective perception of self-efficacy, self-management and improve health status.

Outcome measures: Primary outcomes were consent/recruitment, website usage and completion of outcome measures. Secondary outcomes included Partners in Health (PIH) questionnaire, the Chronic Disease Self-Efficacy Scale, the SF36 and the E-Health Impact Questionnaire. Participant blinding postrandomisation was not possible. The analysis was blind to allocation.

Results: Recruitment target exceeded. 148 participants randomised (73 intervention group). Age range 19–84 years; 59% female. 121 of 148 (84%; 62 intervention group) followed up. The median number of logins was 2 (IQR 2–3, range 1–48). Minimal differences of change from baseline between groups; both showed improvement in health state or management of their condition with no significant differences between arms. No adverse events.

Conclusions: Recruitment and retention confirmed feasibility. The trends towards improved outcomes suggest that further research on digital interventions based on exposure to others' personal experiences may be of value in the self-management of chronic asthma.

Trial registration number: ISRCTN29549695; Results.

Strengths and limitations of this study

- Self-management and long-term control of mild to moderate asthma is often poor and tailored online information has been shown to be appealing and effective in the self-management of chronic health conditions.
- Patients proactively choose to view online patient experiences that provide immediate and relevant value and this content is a viable alternative or supplement to traditional 'facts and figures' information.
- The EXPERT asthma intervention website was developed with extensive input from adults with asthma, whose synthesised experiences of self-management formed the intervention content.
- In contrast to previous trials of a similar nature, recruitment rates were high; however, future work needs to consider how to deliver such an intervention in a more pragmatic fashion reflecting 'real world' internet use, and assessing the value of such an intervention as an adjunct rather than an alternative to other sources of information.

BACKGROUND

Asthma is a major public health problem which is frequently underdiagnosed and undertreated. Globally, the prevalence of asthma is rising, as is the corresponding burden on healthcare systems.[1] With symptom control as the primary goal of treatment, the extent to which asthma patients play an active role in the day-to-day management of their condition is directly associated with improved outcomes.[2] However, self-management and long-term control of mild to moderate asthma is often poor and this has been linked to several factors, including complexity of the condition, reluctance to accept diagnosis of a chronic condition, over-reliance on health professionals and simple forgetfulness.[3] While effective management

of symptoms through appropriate use of medication is vital, education and information play a significant role, with tailored information being shown to be highly effective in asthma care.[4] [5] Asthma patients report unmet information needs and are generally keen to participate in the decision-making process.[6] A disconnection has been reported between patients and healthcare providers views about what patients need to know.[7] [8] A tailored, personalised and proactive approach to symptom management has the potential to improve asthma outcomes primarily by encouraging adherence to medication,[9] but formal adoption of this approach is wanting.

In recent years, there has been continuous growth in the use of the internet for health information across Europe,[10] [11] and the role and nature of digital health resources has evolved. Websites are no longer static repositories of information and health resource consumers are now likely to be 'prosumers'—simultaneous consumers and creators of online material—with proactive engagement with online resources, particularly those containing patient-focused content, especially high among those with one or more chronic conditions.[12] While many early asthma web interventions and digital resources failed to meet patients' needs and expectations in terms of usability and content,[13] an online interdisciplinary approach has been consistently demonstrated as an attractive and effective source of long-term support for asthma management[13–16] when compared with usual care. Increasingly, people desire more than traditional forms of fact-based health information and actively go online to seek others' accounts of their own experiences of health and illness,[17] [18] with patients proactively choosing to view online patient experiences that provide immediate and relevant value. In particular, patients experiencing a range of conditions report finding personal testimonials useful in helping them to recognise and reflect on decisions that need consideration, identifying and appraising options, and supporting coping strategies.[19] There is now a limited but emerging literature looking at the value of novel digital tools which attempt to harness this narrative, experiential information from peers to influence health attitudes and behaviour.[19–23]

However, questions remain regarding the composition of online health information and understanding of what works well, how and for whom. Determining a digital intervention's 'active ingredients' is complex but important: this study attempts to harness and isolate the impact of exposure to online experiential information. Self-management is an established approach to controlling asthma,[24] and the content of asthma self-management education is well described in UK and international clinical guidelines.[25] [26] However, despite the reported effectiveness of asthma self-management, promotion and uptake remains low among patients and healthcare professionals. Factors known to impact on effective self-management include suboptimal social support and perceived ease of access to healthcare, together with a lack of knowledge about how to manage the condition, misunderstandings about therapy, concerns about medication and perceived difficulty with 'fitting' self-management into daily life.[27] [28]

Although digital tools have been shown to hold promise in supporting self-management, the best way to communicate information and support through such tools is often unclear.[15] [29] The theoretical foundation of the EXPERT intervention was underpinned by a conceptual review[18] which suggested that observing and participating in the online sharing of personal experience of health and illness could be beneficial in self-management. The conceptual review identified seven 'domains' in which online patients' experiences could affect health: finding information, feeling supported, maintaining relationships with others, affecting behaviour, experiencing health services, learning to tell the story and visualising disease. It was hypothesised that the EXPERT asthma intervention could achieve impact across these domains through the provision of experiential, contextualised information. Exposure to such information could help participants feel more informed about their condition, less alone in managing it and more able to manage relationships with significant others through the mechanisms of social support, social comparison and self-efficacy. In addition, the free-form, non-tunnelled approach to navigating the EXPERT website encouraged recursive engagement with information chosen by the participant as being of particular relevance to them and their specific needs.

Evidence demonstrates that sharing practical and experiential information online is an important part of health-related internet use and that accessing such content is particularly valued by certain patient groups.[18] The potential for personal stories to improve perceived support has been noted across various health conditions, such as HIV/AIDS,[30] prostate and breast cancers[31] and fibromyalgia.[32] However, far less how is known about how people with asthma view online patient experiences and how they make use of the information they find.

The theoretical review by Ziebland and Wyke[18] formed the foundation for a programme of work undertaken to develop and test online interventions intending to harness the value of other people's experiences as a new mechanism for delivering health benefit. In this paper, we therefore describe the findings from the first randomised controlled trial (RCT) of a novel 'experienced-based' online intervention for the self-management of chronic asthma. The primary aim of this study was to determine the feasibility of trialling this new approach as an asthma self-management intervention. The secondary aim was to report the effect of the intervention and comparator websites on various self-reported outcomes, including measures of self-efficacy, self-management and health status. Ethical approval for this study was provided by the NHS Health Research Authority Research Ethics Committee, reference 13/NW/0162.

METHODS

The trial protocol is provided as online supplementary file 1.

Settings and participants

People with chronic asthma were recruited from nine primary care practices in two regions of England between June 2013 and November 2013, facilitated by the local primary care research networks. Individuals were eligible if they had been clinically diagnosed with asthma as coded in their primary care electronic record and prescribed inhaled corticosteroids for at least 3 months in the previous year, were aged 18 years or over, lived in England and had internet access. The local primary care research network identified primary care practices on our behalf and practices were sent the inclusion and exclusion criteria and asked to identify patients who met the criteria. Individuals were then sent an information pack. GPs excluded people who were unable to read English, who were terminally ill or had another significant disease or disorder likely to affect their ability to participate in the study. For full inclusion criteria, see box 1.

Study design and procedure

The study formed part of a larger programme of work investigating the value of online patient experiences.[33] We conducted a phase II pilot randomised single-blind trial with the aim of assessing the feasibility and impact of patient-experience (PEx)-based websites compared with matched health information websites that did not contain experiential information. We did this for three conditions: smoking cessation; asthma; and caring for someone with multiple sclerosis. Target recruitment was 300 participants, 100 participants per condition. The

---

Box 1   Inclusion and exclusion criteria

Inclusion criteria
Male or female aged 18 or over
People who have been clinically diagnosed asthma as coded in their primary care electronic record, and who have been pre-scribed inhaled corticosteroids for at least 3 months in the previous year
Willing and able to give informed consent for participation in the study
Resident in England
Have access to the internet and are able to use websites
Exclusion criteria
People who are terminally ill
People who cannot understand English
People who have previously entered the study under the same/another condition
People who have another significant disease or disorder which, in the opinion of the GP, may either put that person at risk because of participation in the study, or may influence the result of the study, or affect that person's ability to participate in the study
Another person in the household is already enrolled in the study

---

smoking cessation and carers case studies will be reported separately. To minimise the risk of contamination across the three studies, each recruited in different settings and only one person per household was eligible to take part in any of the three studies.

Participants who indicated interest and met the inclusion criteria were sent a patient information sheet and consent form by post to be signed and returned to the research office in a reply-paid envelope. Once consent had been received, participants' details were entered into a secure Trial Management Portal and they were emailed a unique 'Welcome Code' with a link to the trial registration web page (see online supplementary file 2). An automatic email was generated if the participant had not used their code within a week, inviting the participant to visit the trial registration page. Participants who no longer wished to take part could simply ignore this reminder. The email contained a link to access the trial registration page where the participant was invited to complete online baseline questionnaires. Completion of baseline measures generated an invitation to create a unique user ID and password and randomisation to access either the intervention or comparator website, for a period of 2 weeks. Randomisation used a computer-generated random number sequence in a 1:1 ratio and was carried out by stratified (on the three conditions) block randomisation with varying block sizes. A randomisation list was generated and uploaded to the online trial portal to ensure treatment concealment. The investigators were not aware of the randomisation result on the system. The randomisation list, which was password-protected, was kept in confidence.

Participants were able to logon and access the website interventions as much or as little as they wanted. At the end of the 2-week period, participants were invited (by email) to complete final follow-up measures, online. Up to two emails and one telephone call were used to remind those who did not initially respond. Participants' usage of their allocated website was also tracked. In addition to the statistical analysis, we also conducted interviews with participants in this trial and with participants in the two other trials exploring the value of online personal experiences and a joint analysis of these will be reported separately. Participants could not be blind to the nature of the website to which they were allocated, but they did not know whether they were receiving the comparator or the intervention website, only that we were evaluating two approaches to giving health information. The analysis was blind to allocation.

Intervention design

The intervention was a multimedia website developed by the University of Oxford Health Experiences Research Group and the Healthtalk.org charity. An advisory panel of lay representatives, leading researchers and clinicians also provided extensive input. The website included thematic analyses of key topics from interviews with a purposive sample of 40 people with asthma about their

experiences of their condition.[34] Topics are illustrated with interview extracts in short video, audio and written formats. Video and audio extract varied in length but were typically 2 min long. Examples of the 25 topics published on the website include 'early signs and symptoms', 'what asthma feels like', 'dealing with health professionals', 'emotions and coping' and 'advice to others'. The content was presented on the website in such a way that users were able to browse topics according to relevance and interest. The content was not personalised to individual users and information flow was not guided or 'tunnelled' in any way: all intervention users experienced the same website and could navigate content in any chosen order. To maintain a stable intervention, we did not include user interactivity that could change the content of the website, other than the option to provide feedback to the research team. Users were able to comment on and rate each page if desired.

To compare this intervention site with a 'gold standard' matched alternative, we provided a control website based on 'facts and figures' about asthma self-management. We constructed a new site which closely resembled the design and features of the intervention yet was populated with the asthma self-management information taken from NHS Choices (http://www.nhs.uk), as the authoritative provider of online health information in the UK. Screenshots of both sites are provided as online supplementary file 3.

Outcome measures

As a feasibility study, our primary measures concerned the number of participants consented and recruited, the usage of the websites (in terms of numbers of logins, page views and time on site) and the numbers with completed outcome measures or lost to follow-up. Secondary outcomes used the following self-report questionnaires. The Partners in Health (PIH) measure is a 12-item questionnaire which asks participants to rate how well they look after themselves and manage their health condition, on an 8-point scale. The Chronic Disease Self-Efficacy Scale (CDSES) is a 6-item questionnaire which asks respondents to rate their confidence in being able to undertake certain activities, on a 10-point scale. A single-item asthma control question was included, which asked how participants rated their asthma control over the past 2 weeks. The SF36 (including physical and mental dimensions and all subscales) measures health status. Finally, we used the E-Health Impact Questionnaire (eHIQ), a validated measure which captures the attitudes of respondents towards the website they have recently viewed, giving scores on three subscales: confidence and identification, information and presentation, and understanding and motivation.[35]

Sample size and statistical analyses

The target sample size for this asthma study was 100 participants. The primary determinant of this sample size was to demonstrate feasibility. In terms of effect sizes, based on a balanced randomisation of the intervention:

comparator groups in a ratio of 1:1 (ie, 50 intervention, 50 comparator), the study would detect potential large effects of the intervention: for dichotomous outcomes, these were equivalent to relative risks of 2.1 or above for a baseline rate of 30% or less, given an α of 0.05 and 90% power; for continuous outcomes, these detectable differences would be of the order of 0.4 SDs based on the same power and significance. Feasibility outcome measures were summarised using descriptive statistics such as rates reported as percentages. Formal hypothesis testing was not performed since this was a feasibility study and was not intended to power for assessing evidence of significant treatment effect, but estimated difference in outcome measures of efficacy and corresponding 95% CIs were calculated using analysis of covariance (ANCOVA) adjusting for baseline values.

RESULTS

A total of 200 invitations were sent in response to expressions of interest in the study, and 150 individuals (75%) completed registration (ie, consented and completed baseline questionnaires). Two participants withdrew before randomisation, leaving 148 randomised participants (recruitment rate of 148/150=99%). Seventy-three of these (49%) were allocated to the patient experience website. Of the randomised participants, 25 of 148 (17%) were lost to follow-up. See CONSORT flow diagram (figure 1).

The baseline demographics and asthma status of randomised participants are presented in tables 1 and 2. Participants' baseline asthma status was measured using the Asthma Control Test (ACT), which measures control using five items with a five-point scale. Over 90% of the cohort was white, and the majority reported good to excellent internet abilities. Eighty-seven of the 148 participants (59%) were women. Most participants did not have major problems with their asthma. The majority reported that their asthma had not prevented them from getting things performed at home or at work over the past 4 weeks, with 80.4% stating that they had experienced very little or no shortness of breath. The use of reliever inhalers was spread among the sample, with 25.7% using a reliever inhaler at least once daily and 14.2% using one 2–3 times/week. About 31.8% of the sample had not used an inhaler at all in the previous 4 weeks. About 82.4% of the sample reported that their asthma was 'well' or 'completely' controlled.

The usage of the websites is shown in table 3 and online supplementary figures S1 and S2. Usage data refer to the number of logins, total number of pages visited and time spent on the participant's allocated site. It does not include time spent completing baseline or follow-up measures. The median number of logins in the 2-week period for both sites was 2, and the median number of page views was 14 for the intervention site and 15 for the comparator site. The median duration of the use of the intervention site was 15 min, and for the
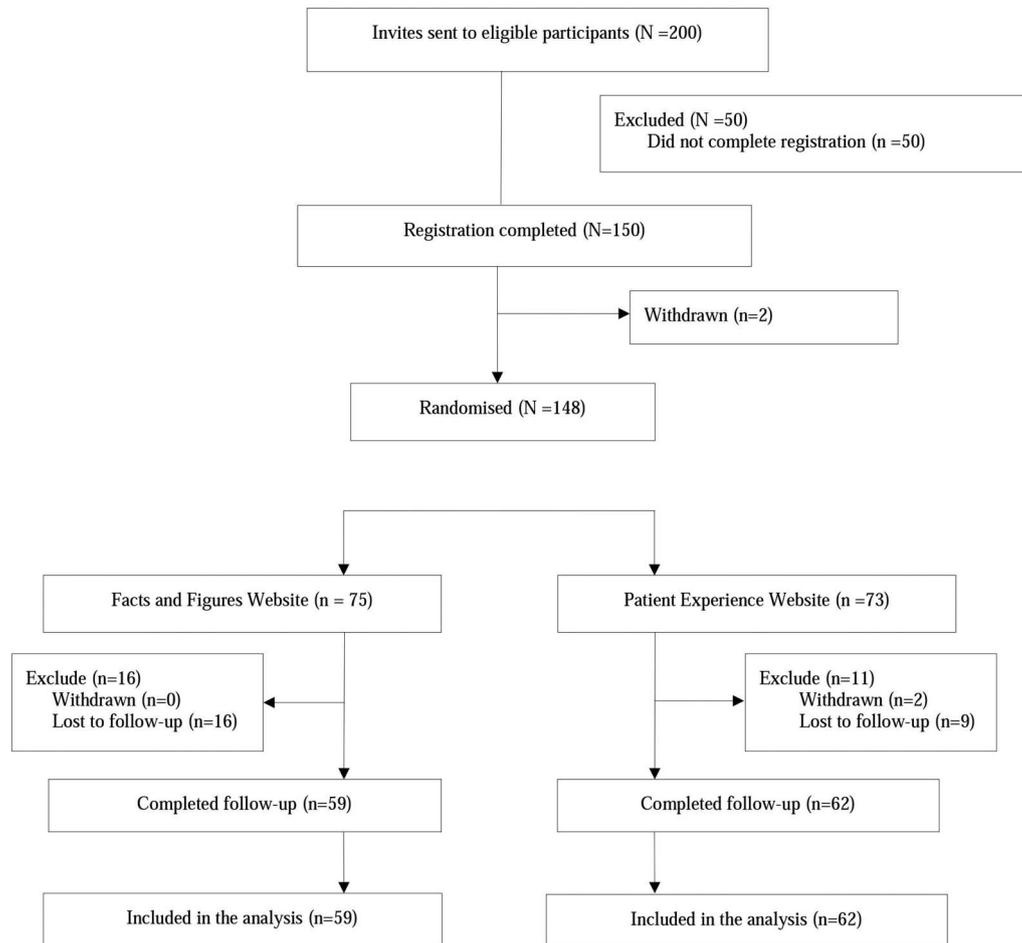

Figure 1 CONSORT flow diagram.

comparator site was 19 min. Three users never logged in to their allocated site, all in the intervention group.

The PIH baseline mean score (SD) for the intervention group was 6.69 (0.888) and for the comparator group 6.81 (0.864); at 2-week follow-up, these scores were 6.84 (0.863) and 6.97 (0.996), respectively. Both groups had high mean PIH scores, indicating good management of their condition. The mean (SD) change from baseline was an increase of 0.06 (0.61) in the intervention group and an increase of 0.03 (0.64) in the comparator group. Treatment effect (mean differences with CI) estimated using ANCOVA adjusting for baseline mean PIH scores showed that there was very little difference between the intervention and comparator group (the former on average scored lower compared with their baseline by −0.02 points, 95% CI −0.25 to 0.21), although CIs are wide and incorporate values representing an increase in the intervention group.

The findings from the other exploratory comparisons of asthma-specific outcome measures are shown in tables 4 and 5. Table 4 shows the baseline and follow-up scores and change scores for the CDSES. The ANCOVA analysis estimated the mean difference between groups. Since the model was adjusted for baseline score, the estimated adjusted treatment effects should be identical on

change scores or follow-up scores. Table 5 shows the answers provided for the single-item control question. For these measures, there were very minor differences between groups with no clear indication of a differential effect between groups.

Table 6 shows that the e-HIQ part B scores were also very similar between groups.

All participants showed an improvement in overall health state from baseline in the Physical and Mental component of the SF36, with a greater improvement in overall health state seen in the intervention group. The mean differences between the groups were compared adjusting for baseline scores (ANCOVA analysis, n=119 participants with full data), showing that the intervention group on average saw an increase in PCS of 0.20 points (95% CI −1.45 to 1.85) compared with the comparator group. Similarly for the MCS, the intervention group on average saw an increase of 0.85 points (95% CI −1.07 to 2.75) compared with the comparator group.

DISCUSSION
The primary objective of this study was to determine the feasibility of using the RCT paradigm to measure the impact of a novel intervention using patient experiences

Table 1 Baseline demographic of the study population

	Comparator (n=75)		Intervention (n=73)

for self-management of chronic asthma. Recruitment and consent rates were high in this study, demonstrating trial feasibility. It is possible to speculate that strong response rates were achieved thanks to the combined actions of a proactive primary care research network and engaged general practitioners who were able to identify a condition which is readily coded in the primary care system. The intervention was delivered successfully, and there were no adverse events or protocol deviations. As is frequently seen in trials of fully automated online interventions, actual use of the intervention was relatively low: the median number of logins was 2 and the median amount of time spent on the site was 17 min, although there was wide variation, with usage data skewed by some participants spending a long time on the website. Collection of the usage data was valuable in exploring whether or not simple exposure to the website was sufficient to have an effect on the outcome measures and given the low level of usage observed, future work needs to maximise user engagement with the intervention. We were not able to record which specific pages of the intervention were most used, and again it would be valuable in future work to understand more about this when interpreting the effect of using the website. Retention rates at 2 weeks were moderately high (82%). Future work could include additional forms of automated contact such as text message prompts and reminders to reduce attrition further, without compromising the cost advantage of having no face-to-face contact.

This study was not designed to assess efficacy, and comparisons between randomised groups showed no significant differences on any of the measures. This is not surprising as the comparator group received access to what is considered to be excellent factual information about management of chronic asthma. Importantly, there were no adverse events from the novel intervention. Future work should take an explicitly pragmatic approach: one way of doing this would be to explore whether the experiential element could be incorporated as an adjunct rather than as an alternative, investigating whether experiential information has added value alongside 'facts and figures'.

Future work should consider the nature of how the sites are used. Allocating participants to a 2-week 'dose' of a website and then measuring its impact does not reflect real-world information behaviour or everyday internet use. Future work needs to reflect 'real-life' engagement with digital resources. This is challenging within an RCT design which generally packages websites as a static experience, so that everyone in the group receives the same intervention. In practice, people search, reflect on, personally curate and 'consume' multiple information sources within an off-line and online landscape in multiple ways at different stages of an illness. Further theoretical and methodological work may be needed to consider the issues of 'dosage' and 'exposure' in the context of online health information. For example, future work could explore the potential value to users of being able to contribute to an experience-based intervention: the current study used a set of personal accounts which had been solicited and

†Units of total duration was recorded in minutes, for participants with 0 min recorded, we approximated this to 0.5 min.

curated so as to comply with the RCT paradigm. In reality, people who are managing chronic asthma may wish to contribute and comment as well as look at those from others; this may offer more realistic interaction and reflects the real-life evolution of such websites.

It is important to note characteristics of the cohort which would likely influence outcomes. Although participants were eligible if they had been clinically diagnosed with asthma and prescribed inhaled corticosteroids for at least 3 months in the previous year, the vast majority of participants had lived with asthma for much longer. No recently diagnosed patients were randomised. Most of the people who volunteered to take part were experienced in managing their condition and had their

Not reported*	27	(18.2)	16	(21.3)	11	(15.1)
Poorly controlled	2	(1.4)	1	(1.3)	1	(4.1)
Somewhat controlled	11	(7.4)	8	(10.7)	3	(4.1)
Well controlled	61	(41.2)	26	(34.7)	35	(47.9)
Completely controlled	47	(31.8)	24	(32.0)	23	(31.5)

*Lost to follow-up.

Table 6 Mean (SD) of E-Health Impact Questionnaire (eHIQ) part 2 scores for the intervention and comparator group at 2-week follow-up

	Comparator (n=57/75)	Intervention (n=61/73)	Unadjusted mean difference	95% CI
eHIQ part 2 overall scores	67.3 (12.46)	65.8 (11.29)	−1.473	−5.802 to 2.855
Subscales				
Confidence and identification	59.7 (17.03)	58.7 (14.67)	−1.052	−6.836 to 4.732
Information and presentation	76.1 (11.38)	74.5 (10.56)	−1.462	−5.412 to 2.487
Understanding and motivation	64.3 (15.22)	63.9 (13.66)	−0.334	−5.535 to 4.868

asthma well controlled. They were also, not surprisingly, people who were comfortable and confident about using the internet. Thus, while they were willing and able to take part in a study of online health information, they were not a group who were likely 'in the real world' to be searching online for health information or connection with other people living with asthma, in order to support their own asthma management. This has clear implications for further research: how do you recruit those people who perhaps are less likely to be motivated to take part in the research but are more likely to need help with self-

management? Further work is required to identify which people with asthma are most likely to benefit from such an intervention: for example, experiential information of this type and for this condition may be best suited to those who are newly diagnosed or experiencing a change in symptoms.

CONCLUSION
Asthma remains a major public health problem internationally and can profoundly impact on physical and

Open Access

psychological well-being. Effective self-management of chronic asthma is associated with improved outcomes. The sharing of personal experiences online is a relatively new phenomenon and we have attempted to examine the value of this in a novel intervention to support self-management as part of an RCT. We have demonstrated that this is feasible and not shown any harm from the intervention, compared with a gold standard 'facts and figures' website. However, future work needs to consider how to deliver such an intervention in a more pragmatic fashion reflecting 'real world' internet use, and assessing the value of such an intervention as an adjunct rather than an alternative to other sources of information. Future work, as with all new self-directed internet interventions, is also needed to determine the best methods to maximise engagement and adherence.
